Description

The present invention relates to an oral pharmaceutical controlled release multiple units dosage form in which individual units containing an active substance are surrounded by a coating which releases the active substance through diffusion.

Technical background

The term "controlled release multiple units formulation" (Bechgaard & Heggermann Nielsen, 1978) indicates a pharmaceutical formulation comprising a multiplicity (typically at least 100) of individual coated (or "microencapsulated") units contained in the formulation in such a form that the individual units will be made available from the formulation upon disintegration of the formulation in the stomach of animals, including humans, who have ingested the formulation. Typically, the multiple units formulation may be a gelatin capsule or a tablet which disintegrates in the stomach to make available a multiplicity of coated units.

Controlled release multiple units formulations aim at a controlled release of active substance in a predetermined pattern to reduce and delay the peak plasma concentration without affecting the extent of drug availability. Due to a lower peak plasma concentration, the frequency of undesirable side-effects may be reduced, and due to the delay in the time it takes to obtain the peak plasma concentration and the prolongation of the time above the therapeutically active plasma concentration, the dosage frequency may be reduced to a dosage taken only twice or once a day, in order to improve patient compliance.

A further advantage of the controlled release multiple units dosage form is that high local concentration of the active substance in the gastrointestinal system is avoided, due to the units being distributed freely throughout the gastrointestinal tract.

Drug release from a controlled release dosage form is generally controlled by a coating outside an active core. The release can be achieved

- a) by diffusion: the coating swells in aqueous environment so that the active substance can diffuse through the stagnant liquid phase contained in the coating polymer, or
- b) by osmosis: the coating is semipermeable, i.e. only water can penetrate the coating polymer and dissolve the active substance, this will lead to a pressure buildup inside the coating, in order to allow the active to be released from the unit a hole or channel with a well defined area must be formed in the coating, this can be achieved either by laser drilling (SE patent 435 897 - US patent 4256108 to Alza) or by incorporation of a substance which will form the channels by erosion after ingestion (US patent 4687 660 and European Patent Application 0171 457 to Wellcome), should the coating have any weak spots or cracks in it these will increase the release area and as a result give varying dissolution rates for different units, i.e. zero order release will not be achieved for the whole dose, or
- c) by erosion: the coating will disintegrate by a process dependent on, e.g. enzymes or pH and leave the active core exposed to rapid dissolution. The importance of a pH independent diffusion with respect to obtaining a reproducible rate of availability and to minimizing intra- and intersubject variations is known (GB Patent No. 1,468,172 and Bechgaard & Baggesen, 1980). It is also known that controlled drug release in vivo can be achieved through an erodible process by enteric coating of a multiple units dosage form (Green, 1966; McDonald et al., 1977; Bogentoft et al., 1978).

The present invention deals with multiple units dosage forms controlled by diffusion membranes. Contrary to previously known diffusion membranes used for multiple unit dosages the membrane according to the invention is non-swellable in water and gastrointestinal fluids. Furthermore the polymer used must be insoluble in and impermeable to water and pores are formed in the membrane after ingestion by a pH independent erosion process. The pores will give the coating a sponge-like appearance and will be filled with stagnant liquid where the active substance can diffuse out from the core.

Disclosure of the invention

A number of coatings employed in connection with pharmaceutical controlled release multiple units formulations have been observed to suffer from the disadvantage that they change their release characteristics in the course of time. This means that it is not possible to maintain a reproducible release rate of an active substance contained in the multiple units formulation as a variable release rate has been observed for such coatings. In accordance with the present invention, it has unexpectedly been found that by selecting a special type of controlled release system which has not previously been used or disclosed for multiple units formulations many problems connected to multiple units formulations can be avoided.

In macro scale, i.e. for tablets, controlled release systems based on coatings containing pore-creating substances has been disclosed in, e.g. the GB Patent No. 1,186,990, the US Patent No. 3,538,214 and in the US Patent No. 4,557,925. The present release system is based on the principle of coating a core including an active substance with a film essentially consisting of a polymer that is insoluble in and impermeable to water and gastrointestinal fluids, and in which a watersoluble pore-creating substance is randomly distributed. It is also required that the polymer is non-swellable in water and gastrointestinal fluids. When applying this controlled release system to multiple units formulations it was unexpectedly found that important advantages could be obtained.

It was thus found that it is possible to coat different types of particles, including crystals, in ordinary coating equipment, i.e. in different types of standard equipment normally available in a pharmaceutical industry. From this follows that the manufacturing process is comparatively easy and cheap. Additionally it was found that a uniform essentially zero order controlled release rate could be obtained also when relatively non-uniform particles were used as cores. This is usually not the case in conventional multiple units controlled release formulations. For example diffusion controlled release from multiple units where the polymer swells are dependent on the thickness of the diffusion layer which will differ with time since the polymer will release the active substance while the swelling continues. This will lead to different release rates at the beginning and end of the release period which will result in a release more similar to first order release than zero order. Osmotic controlled multiple units on the other hand are dependent on both the ability of the substances in the core to draw water into it, which may lead to lowered release rate at the end of the release period if the osmotic active and drug active substances are not the same, and the coating quality, which, if it has any weak spots or cracks in it, increases the release area. Such defects give varying dissolution rates for different units, i.e. zero order release will not be achieved for the multiplicity of the units contained in a dose.

Another advantage of the present invention is the possibility of adjusting the release rate by changing the film thickness. In currently commercially used multiple unit systems this possibility seems to exist in a rather unpredictable manner and only up to a certain film thickness. In the present system, on the contrary, an essentially linear correlation exists between the release rate and the film thickness. This means that for a given type of film the release rate decreases when the film thickness increases in a proportional manner in accordance with Fick's first law of diffusion.

It is also possible to change the release rate by changing the ratio between the pore-creating substance and the coating polymer. This gives the present system a unique possibility to utilize active substances with very different solubilities, which is a great advantage over the existing multiple units controlled release systems.

Thus, one aspect of the invention relates to an oral pharmaceutical controlled release multiple units formulation characterized by individual units containing an active substance, which units are provided with an outer coating consisting essentially of a polymer that is insoluble in, impermeable to and non-swellable in water and gastrointestinal fluids, and a watersoluble pore-creating substance which is randomly distributed in the polymer. Another aspect of the invention is a formulation in which units of the type described above are combined with uncoated units which comprise the same or another active substance for instant release thereof, and/or with non-diffusion coated units which have been provided with a coating selected from hydrophilic coatings, hydrophobic coatings, waterbased coatings and organic coatings imparting desired properties to the unit such as acid or alkali resistance, storage stability, taste masking, light stability, colouring, improved processability, etc. The ratio between diffusion coated and uncoated or non-diffusion coated units in the composition may be adjusted according to, for instance, the desired release characteristics of the composition, but is preferably in the range of about 10:90 to 90:10 of diffusion coated units to uncoated or non-diffusion coated units.

The oral pharmaceutical controlled release multiple units formulation according to the invention will typically be a gelatin capsule containing a multiplicity of the units, typically more than 100, a sachet containing a multiplicity of the units, typically more than 500, or a tablet made from a multiplicity of the units, typically more than 100, in such a manner that the tablet will after ingestion disintegrate in the stomach into a multiplicity of individual units. In each of the three above mentioned formulations the units will be freely distributed throughout the gastrointestinal tract shortly after ingestion.

Detailed description of the invention**Coating**

5 The coating polymer should have good filmforming and adhesive properties, and should be readily soluble in organic solvents such as acetone, methylene chlorid, methylethyl ketone or mixtures of acetone and ethanol or methylene chloride. Suitable polymers are non swelling cellulose derivates, acrylic polymers and vinyl polymers. The coating polymer is a polymer containing 80-95% weight by weight vinyl chloride, 1-19% weight by weight vinyl acetate and 0-10% weight by weight vinyl alcohol. Preferably containing 88-
10 94% weight by weight vinyl chloride, 2-5% weight by weight vinyl acetate and 3-5% weight by weight vinyl alcohol.

Preferably plasticizers also are present in the coating. The amount may vary between 1 to 50% weight by weight of the coating polymer, preferably between 10 and 40%. Examples of suitable plasticizers are acetyltributylcitrate, polyethylene glycol, blown castor oil and glyceryl triacetate. Furthermore, the coating
15 may include sodium bicarbonate as stabilizing agent in amounts between 1 and 20% weight by weight of the coating polymer, preferably 5 to 15% weight by weight of the coating polymer.

The pore-creating substance used according to the present invention should be highly water-soluble, insoluble in the solvent used for coating, pharmacocologically acceptable and essentially free from own pharmacological effects in the amounts used. Especially preferred are sugars such as saccharose and
20 lactos, and salts such as sodium chloride.

The particle size of the pore-creating substance may vary between 0.1 and 100, preferably between 0.5 and 50 μm . The ratio between the amount of pore-creating substance and coating polymer depends on the desired dissolution rate. Generally the ratio should be between 0.05 and 5, preferably between 0.1 and 2.

The coating thickness is also dependent on the desired dissolution rate. It may vary between 5 and 300
25 μm , preferably 10 and 150 μm .

Cores

The individual units of the multiple units formulations according to the invention are coated cores
30 consisting of crystals or pellets. The crystal units are substantially monolithic crystals. The pellets are constituted by a combination of active substance and excipients. One major type of pellets consists of an excipient seed-particle with active substance applied to its surface. Typical pellets of this type are the so-called "non-pareil" pellets where the seeds are in the form of spherical particles of saccharose. In another pellet formulation principle of this type the seeds are in the form of chrystalline saccharose. Another major
35 type of pellets consists of cross-sectionally substantially homogenous particles prepared e.g. wet-granulation or extrusion.

The diameter of the cores is normally about 0.1-1.5 mm, preferably about 0.4-1.2 mm, preferably with a range of about 0.4 mm within a specific formulation.

40 Active substance

The active substance in the formulations according to the invention may be any active substance which is advantageously administered in a controlled release multiple units formulations. Examples of suitable active substances are found among almost all therapeutic groups, including diuretics, antiepileptics,
45 sedatives, antiarrhythmics, antirheumatics, β -blockers, vasodilators, analgesics, bronchodilators, hormones, vitamins, oral antidiabetics, antibiotics, antihypertensives, antiinflammatory drugs, antimicrobial agents and antidepressants, polypeptides, enzymes and mucopolysaccharides.

As examples of active substances may be mentioned phenylpropanolamine, potassium chloride, quinidine salts, lithium carbonate, acetyl cystein, depyridamol, theophylline, choline theophyllinate, dextropropoxyphene, dextromethorphan, salbutamol, terbutaline, digoxin, furosemide, propranolol, ibuprofen,
50 lidocaine, mepyramine, morphine, nitroglycerine, clonidine, disopyramide, verapamil, captopril, prazosin, nifedipine, diltiazem, paracetamol, indomethacin, ticlopedine, oxybutynin and noscapine.

Among these substances, some are characterized as having a pH-independent solubility, others as having a pH-dependent solubility. Active substances having a pH-dependent solubility are preferably
55 incorporated in cores in combination with buffering substances such as sodium bicarbonate, citric acid, succinic acid or tartaric acid, in order to obtain a dissolution of active substance which is substantially independent of the gastrointestinal pH variations through which the units will pass.

Method

Generally the method of producing the coated multiple unit preparation according to the invention comprises the steps of dissolving the polymer in a solvent, preparing a suspension of the pore-creating substance, mixing the suspension of pore-creating substance and the solvent solution of the polymer to form a coating fluid, prepare multiple unit cores containing an active substance in the form of crystals or pellets, applying the coating fluid to the core units, and drying the units in order to evaporate the solvent and provide polymer-coated multiple units having the water-soluble pore-creating substance randomly distributed within the coating.

The solvent for the polymer can be selected from, e.g. acetone, methylene chloride, methylethyl ketone or mixtures of acetone and ethanol or methylene chloride.

The pore-creating particles are micronized either by dry milling or by wet-milling to a defined particle size, preferably between 0.5 μm and 50 μm . The particles are dispersed in solvents such as those previously mentioned, and mixed with the terpolymer solution.

The coating fluid may, as previously stated, include a plasticizer and sodium bicarbonate.

Coloring matter can also be incorporated in the coating fluid, and insoluble coloring materials are preferred.

The coating fluid, in the form of a suspension, is then applied on drug-containing cores. A special advantageous feature is that the coating process can be performed in ordinary coating equipment, i.e. in different types of standard equipment normally available in a pharmaceutical industry. This is due to the good filmforming and adhesive properties of the coating material, and the easiness of solvent evaporation from the system. Examples of such coating equipments are pan coating in sugar-coating pans or perforated film-coating pans, Würster coating, and other fluid-bed coating procedures. From this follows that the manufacturing process is comparatively easy and cheap.

The following examples further illustrate the invention but should not be construed as limiting to the invention.

Example 1

Theophylline is a weak acid ($\text{pK}_a = 8.7$) which is poorly soluble in water. The cores used in this example contain 60% theophylline on non-particles and have a particle size of 0.8 - 1.0 mm. These cores (1.0 kg) are coated with a coating suspension of the following composition:

Terpolymer containing 92% vinylchloride, 4% vinylacetate and 4% vinylalcohol weight by weight	390 g
Micronized succrose (particle size 1-10 μm)	930 g
Acetyl tributyl citrate	89 g
Blown castor oil	68 g
Sodium bicarbonate	34 g
Aceton	ad 10.000 g

The coating suspension is applied on the cores with an airless spray-coating device in a coating pan. Samples are taken after the application of 1.0, 2.0 and 3.0 kg of the suspension.

Table 1 shows the dissolution rate of a dose corresponding to 90 mg theophylline. The dissolution testing is performed according to the USP XXI basket method (100 rpm). There is a linear correlation between the release rate and the coating thickness, and the release rate is essentially independent of the pH. A uniform zero order release rate is observed during the major part of the release time.

Table 1

Time (hours)	Released amount of theophylline (%)				0.1 M HCl
	A	B	C	C	
1		46	18	10	11
2		84	39	24	28
3		98	58	37	44
4		100	76	49	59
5			90	62	73
6			96	73	86
7			99	83	94
8				90	99
9				94	100
10				96	101
11				97	101
12				98	102

A: 2.5 mg coating material per cm² of the cores
 B: 5.9 " " " " " " " "
 C: 9.0 " " " " " " " "

Example 2

Choline theophylline is a salt of theophylline readily soluble in water. The cores used in this example contain 30% choline theophyllinate on sugar crystals and have a particle size of 0.7 - 1.0 mm. These cores (1.0 kg) are coated with a suspension of the following compositions:

Terpolymer containing 92% vinylchloride, 4% vinylacetate and 4% vinylalcohol weight by weight	295 g
Micronized succrose (particle size 1-10 μ m)	930 g
Acetyl tributyl citrate	30 g
Blown castor oil	23 g
Sodium bicarbonate	34 g
Titanium dioxide	59 g
Aceton	ad 10.000 g

The coating suspension is applied on the cores with an airless spray-coating device in a coating pan. Samples are taken after the application of 2.0, 2.5, 3.0 kg of the suspension.

Table 2 shows the dissolution rate of a dose corresponding to 90 mg theophylline. The dissolution rate testing according to the USP XXI basket method (100 rpm). The dissolution rate is considerably higher than in Example 1 due to the much higher solubility of the choline salt of theophylline than of pure theophylline. Despite the higher dissolution rate there is still a linear correlation between the release rate and the coating thickness.

Table 2

Time (hours)	Released amount of theophylline (%) 0.2 M TRIS buffer pH 7.4		
	A	B	C
0.33	96	86	76
0.67	100	99	98
1.00		100	100
A: 3.7 mg coating material per cm ² of the cores B: 4.6 mg coating material per cm ² of the cores C: 5.5 mg coating material per cm ² of the cores			

Example 3

Diltiazem hydrochloride is an ammonium salt readily soluble in water. The cores used in this example contain 44% diltiazem hydrochloride or non-pareils and have a particle size of 0.7 - 1.1 mm. These cores (0.9 kg) are coated with a coating suspension of the following composition:

Terpolymer containing 92% vinylchloride, 4% vinylacetate and 4% vinylalcohol weight by weight	409 g
Micronized succrose (particle size 1-10 µm)	930 g
Acetyl tributyl citrate	70 g
Blown castor oil	52 g
Sodium bicarbonate	34 g
Aceton	ad 10.000 g

The coating suspension is applied on the cores with an airless spray-coating device in a coating pan. Samples are taken after the application of 1.6, 2.3 and 3.0 kg of the suspension.

Table 3 shows the dissolution rate of a doze corresponding to 120 mg diltiazem hydrochloride. The dissolution testing is performed according to the USP XXI basket method (100 rpm). The solubility of this ammonium salt is similar to that of the salt in Example 2. The dissolution rate is therefore also similar. Also here is the linear correlation between the release rate and the coating thickness obvious.

Table 3

Time (hours)	Released amount of diltiazem hydrochloride (%) 0.05 M phosphate buffer pH 7.4		
	A	B	C
0.25	48	34	27
0.50	79	67	56
0.75	91	85	80
1.00	96	91	85
1.25	98	94	91
1.50	99	97	94
1.75	100	98	96
2.00	101	99	97
A: 6.8 mg coating material per cm ² of the cores B: 9.8 mg coating material per cm ² of the cores C: 12.4 mg coating material per cm ² of the cores			

Claims

1. Oral pharmaceutical multiple units formulation comprising individual cores containing a pharmacological active substance, said cores being provided with a coating consisting essentially of a polymer, that is insoluble in, impermeable to and non-swellable in water and gastrointestinal fluids whereby said polymer is a polymer containing 80-95 % weight by weight vinyl chloride, 1-19 % weight by weight vinyl acetate and 0-10 % weight by weight vinyl alcohol, and a watersoluble pore-creating substance, which is randomly distributed in said polymer, whereby said coated cores form units providing an essentially zero order diffusion controlled release rate of said active substance.
2. Formulation according to claim 1, **characterized in** that the polymer is a terpolymer containing 88-94 % weight by weight vinyl chloride, 2-5 weight by weight vinyl acetate and 3-5 % weight by weight vinyl alcohol.
3. Formulation according to any of the claims 1-2, **characterized in** that the pore-creating substance is selected from the group consisting of sugars and salts.
4. Formulation according to any of the preceding claims, **characterized in** that it also comprises uncoated cores containing the same or another active substance for the instant release thereof.
5. Formulation according to any of the claims 1-4, **characterized in** that it also includes non-diffusion coated cores provided with a coating selected from hydrophilic, hydrophobic, waterbased or organic coatings.
6. Method of preparing an oral pharmaceutical multiple units formulation comprising individual cores containing a pharmacological active substance, said cores being provided with a coating consisting essentially of a polymer, that is insoluble in, impermeable to and non-swellable in water and gastrointestinal fluids whereby said polymer is a polymer containing 80-95 % weight by weight vinyl chloride, 1-19 % weight by weight vinyl acetate and 0-10 % weight by weight vinyl alcohol, and a watersoluble pore-creating substance, which is randomly distributed in said polymer, whereby said coated cores form units providing an essentially zero order diffusion controlled release rate of said active substance, said method comprising the steps of dissolving the polymer in a solvent, preparing a suspension of the pore-creating substance, mixing the suspension of pore-creating substance and the solvent solution of the polymer to form a coating fluid, prepare multiple unit cores containing an active substance in the form of crystals or pellets, applying the coating fluid to the core units, and drying the units in order to evaporate the solvent and provide polymer-coated multiple units having the water-soluble pore-creating substance randomly distributed within the coating.
7. Method according to claim 6, **characterized in** that the polymer is a terpolymer containing 88-94 % weight by weight vinyl chloride, 2-5 weight by weight vinyl acetate and 3-5 % weight by weight vinyl alcohol.
8. Method according to any of the claims 6-7, **characterized in** that the pore-creating substance is selected from the group consisting of sugars and salts.

Patentansprüche

1. Orale pharmazeutische, multiple Einheiten enthaltende Zubereitung mit einzelnen, einen pharmakologisch aktiven Wirkstoff enthaltenden Kernen, welche mit einer Schicht versehen sind, die hauptsächlich aus einem Polymer, das kein Wasser und keine Magendarmflüssigkeiten durchlässt sowie darin unlöslich und quellfest ist, wobei das Polymer ein Polymer ist, das 80-95 Gew.-% Vinylchlorid, 1-19 Gew.-% Vinylazetat und 0-10 Gew.-% Vinylalkohol enthält, und einem wasserlöslichen porenerzeugenden Stoff besteht, der im genannten Polymer ungeordnet verteilt ist, wobei die beschichteten Kerne Einheiten bilden, die eine diffusionsgesteuerte Freisetzungsgeschwindigkeit des aktiven Wirkstoffs erzeugen, welche hauptsächlich von nullter Ordnung ist.
2. Zubereitung nach Anspruch 1, dadurch **gekennzeichnet**, dass das Polymer ein Terpolymer ist, das 88-94 Gew.-% Vinylchlorid, 2-5 Gew.-% Vinylazetat und 3-5 Gew.-% Vinylalkohol enthält.

3. Zubereitung nach einem der Ansprüche 1 und 2, dadurch **gekennzeichnet**, dass der porenerzeugende Stoff von der aus Zuckern und Salzen bestehenden Gruppe gewählt ist.
4. Zubereitung nach einem der vorhergehenden Ansprüche, dadurch **gekennzeichnet**, dass sie auch
5 unbeschichtete Kerne umfasst, welche denselben oder einen anderen aktiven Wirkstoff zu dessen
sofortigem Freisetzen enthalten.
5. Zubereitung nach einem der Ansprüche 1-4, dadurch **gekennzeichnet**, dass sie auch nicht-diffusions-
beschichtete Kerne umfasst, welche mit einer Schicht versehen sind, die unter hydrophilen, hydropho-
10 ben, wasserbasierten oder organischen Schichten gewählt ist.
6. Verfahren zur Herstellung einer oralen, pharmazeutischen, multiple Einheiten enthaltenden Zubereitung
mit einzelnen, einen pharmakologisch aktiven Wirkstoff enthaltenden Kernen, welche mit einer Schicht
15 versehen sind, die hauptsächlich aus einem Polymer, das kein Wasser und keine Magendarmflüssigkei-
ten durchlässt sowie darin unlöslich und quellfest ist, wobei das genannte Polymer ein Polymer ist, das
80-95 Gew.-% Vinylchlorid, 1-19 Gew.-% Vinylazetat und 0-10 Gew.-% Vinylalkohol enthält, und einem
wasserlöslichen, porenerzeugenden Stoff besteht, der im Polymer ungeordnet verteilt ist, wobei die
beschichteten Kerne Einheiten bilden, die eine diffusionsgesteuerte Freisetzungsgeschwindigkeit des
20 aktiven Wirkstoffs erzeugen, welche hauptsächlich von nullter Ordnung ist, wobei das Verfahren
folgende Schritte umfasst: Auflösen des Polymers in einem Lösungsmittel, Zubereiten einer Suspen-
sion von dem porenerzeugenden Stoff, Vermischen der Suspension von dem porenerzeugenden Stoff
und der Lösemittellösung des Polymers zur Bildung einer Beschichtungsflüssigkeit, Zubereiten von
multiple Einheiten enthaltenden Kernen, welche einen aktiven Wirkstoff in Form von Kristallen oder
Pellets enthalten, Auftragen der Beschichtungsflüssigkeit auf die Kerneinheiten, und Trocknen der
25 Einheiten, um das Lösungsmittel zu verdampfen und polymerbeschichtete Multipelheiten zu erzeugen,
in deren Schicht der wasserlösliche, porenerzeugende Stoff ungeordnet verteilt ist.
7. Verfahren nach Anspruch 6, dadurch **gekennzeichnet**, dass das Polymer ein Terpolymer ist, das 88-
94 Gew.-% Vinylchlorid, 2-5 Gew.-% Vinylazetat und 3-5 Gew.-% Vinylalkohol enthält.
- 30 8. Verfahren nach einem der Ansprüche 6 und 7, dadurch **gekennzeichnet**, dass der porenerzeugende
Stoff von der aus Zuckern und Salzen bestehenden Gruppe gewählt ist.

Revendications

- 35 1. Formulation pharmaceutique orale à doses multiples, comprenant des noyaux séparés qui contiennent
une substance pharmacologiquement active, lesdits noyaux étant pourvus d'un enrobage constitué
essentiellement d'un polymère qui est insoluble dans, imperméable à, et non gonflable a dans l'eau et
les liquides gastrointestinaux, formulation dans laquelle ledit polymère est un polymère à base de 80 à
40 95 % en poids de chlorure de vinyle, 1 à 19 % en poids d'acétate de vinyle, 0 à 10 % en poids
d'alcool vinylique, et d'une substance porogène hydrosoluble répartie au hasard dans ledit polymère,
lesdits noyaux enrobés, formant des doses unitaires, dont la vitesse de libération réglée par diffusion de
ladite substance active est pratiquement d'ordre zéro.
- 45 2. Formulation selon la revendication 1, caractérisée en ce que le polymère est un terpolymère contenant
de 88 à 94 % en poids de chlorure de vinyle, 2 à 5 % en poids d'acétate de vinyle et 3 à 5 % en
poids d'alcool vinylique.
3. Formulation selon une des revendications 1 et 2, caractérisée en ce que la substance porogène est
50 choisie dans le groupe formé par les sucres et les sels.
4. Formulation selon une quelconque des revendications précédentes, caractérisée en ce qu'elle com-
prend aussi des noyaux non enrobés contenant la même substance active ou une autre substance
active pour libération immédiate.
- 55 5. Formulation selon une quelconque des revendications 1-4, caractérisée en ce qu'elle comprend aussi
des noyaux non enrobés par diffusion, pourvus d'un enrobage choisi parmi les enrobages hydrophiles,
hydrophobes, aqueux ou organiques.

6. Procédé de préparation d'une formulation pharmaceutique orale à doses multiples, comportant des noyaux séparés qui contiennent une substance pharmacologiquement active, lesdits noyaux étant pourvus d'un enrobage constitué essentiellement d'un polymère qui est insoluble dans, imperméable à, et non gonflable dans l'eau et les liquides gastrointestinaux, formulation dans laquelle ledit polymère est un polymère à base de 80 à 95 % en poids de chlorure de vinyle, 1 à 19 % en poids d'acétate de vinyle, 0 à 10 % en poids d'alcool vinylique, et d'une substance porogène hydrosoluble répartie au hasard dans ledit polymère, lesdits noyaux enrobés formant des doses unitaires, dont la vitesse de libération réglée par diffusion de ladite substance active est pratiquement d'ordre zéro, ledit procédé comprenant les étapes consistant à dissoudre le polymère dans un solvant, à préparer une suspension de la substance porogène, à mélanger la suspension de substance porogène et la solution de solvant du polymère pour former un liquide d'enrobage, à préparer des noyaux unitaires multiples, qui contiennent une substance active sous forme de cristaux ou de pastilles, à déposer le liquide d'enrobage sur les noyaux unitaires et à sécher les doses unitaires obtenues, afin d'évaporer le solvant et de fournir des doses unitaires multiples enrobées de polymère et pourvues de la substance porogène hydrosoluble dispersé au hasard au sein de l'enrobage.
7. Procédé selon la revendication 6, caractérisé en ce que le polymère est un terpolymère contenant de 88 à 94 % en poids de chlorure de vinyle, 2 à 5 % en poids d'acétate de vinyle et 3 à 5 % en poids d'alcool vinylique.
8. Procédé selon une quelconque des revendications 6 et 7, caractérisé en ce que la substance porogène est choisie dans le groupe formé par les sucres et les sels.
